&

Plasma Science & Technology Department  
Princeton, New Jersey (USA)

**PPPL Graduate Summer School 2019**

# What is a Plasma?

A *Plasma* is more than a collection of neutrals, ions, and electrons!

What characterizes a plasma (i.e. low temperature plasma)?

1. Quasi-neutral state of existence
2. Collective behavior due to Coulomb forces
3. Energy distribution ( $T_e$  is high, not  $T_i$  and  $T_g$ )
4. Collisional and radiative processes

# Two types of plasmas

High-temperature plasmas or Hot (Thermal) plasmas

$$T_i \approx T_e \geq 10^7 \text{ K}$$

e.g., fusion plasmas

$$T_i \approx T_e \approx T_g \leq 2 \times 10^4 \text{ K}$$

e.g. arc plasma at normal pressure

***Low temperature plasmas*** or Cold (Non-thermal Plasmas)

$$T_i \approx T_g \approx 300 \text{ K}$$

$$T_i \ll T_e \leq 10^5 \text{ K}$$

e.g. low-pressure glow discharge

high-pressure cold plasma

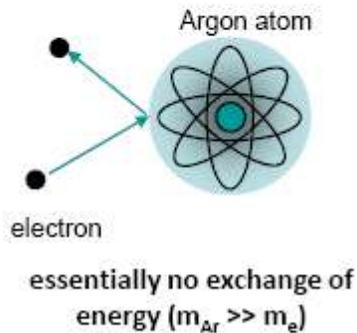

# Collisions generate & sustain the plasma

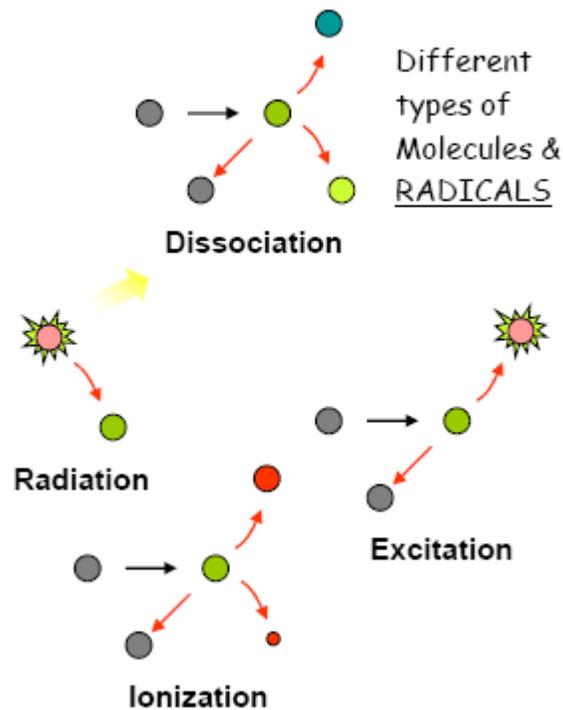

## Elastic collisions

Elastic collisions are frequent in gases  
No energy exchange

## *Collisions in plasmas*

### Inelastic collisions

- Molecules
- Excited molecules
- Ions
- Electrons

Gas  
  
 Plasma

Therefore more and stronger collisions leading to more

ionization, excitation, dissociation and radiation

# Plasma generation

A plasma is generated by supplying energy to a volume of gas to produce pairs of electrons and ions (charge carriers).

- most commonly electrical energy is supplied

Low temperature plasmas are usually excited and sustained electrically by applying

- Alternating Current (AC) power
- Radio Frequency (RF) power
- Microwave (MW) power
- Direct Current (DC) power
  - Pulsed DC power

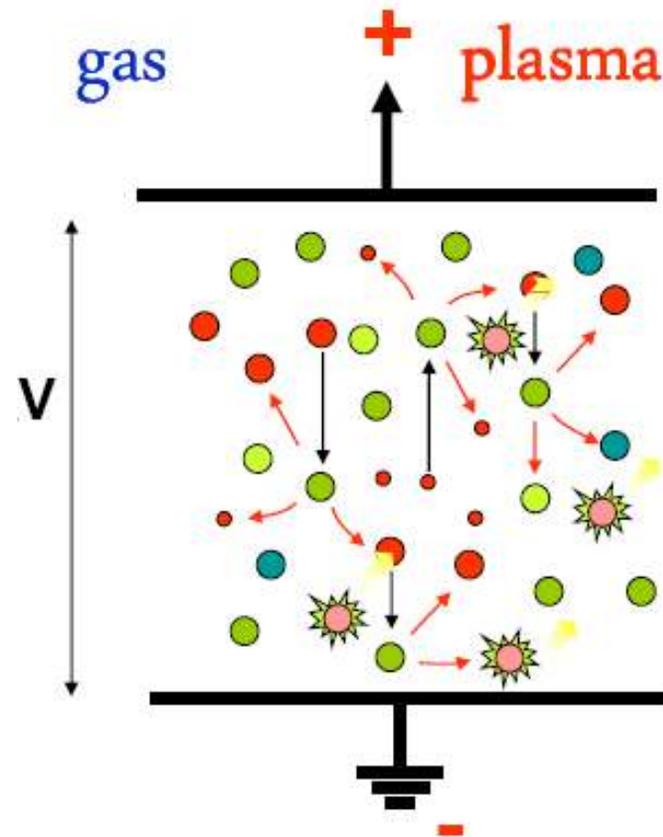

# How do we make plasmas?

Supply Energy!!!  
e.g. Heat transfer, radiation,  
**electric power**...

For many plasma applications,  
an Electric Field is applied to a  
gaseous environment

Plasma or Gaseous Discharge

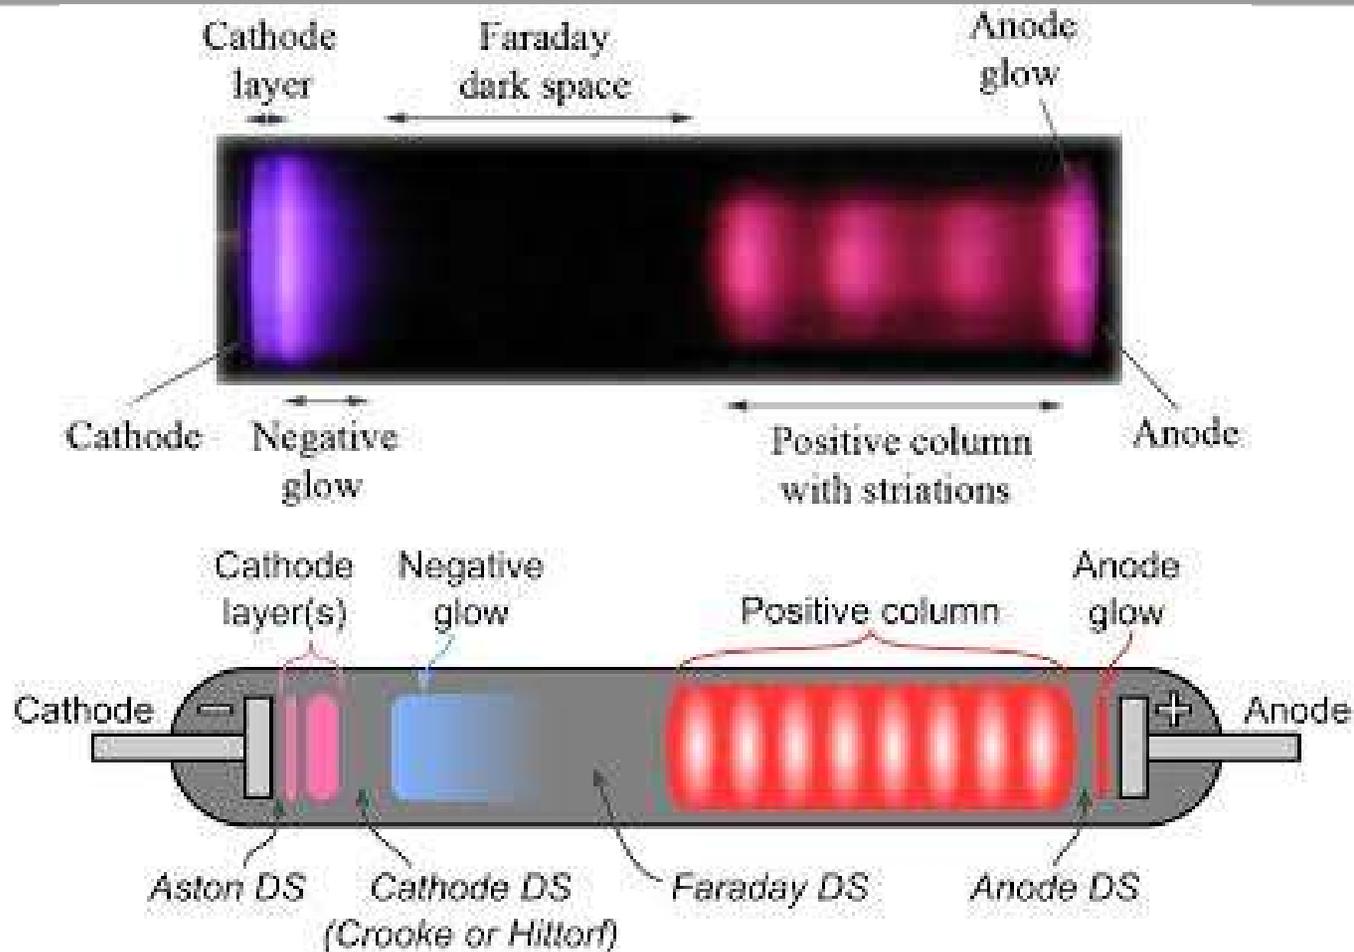

- Molecules
- ☀ Excited molecules
- Ions
- Electrons

# DC Glow Plasma

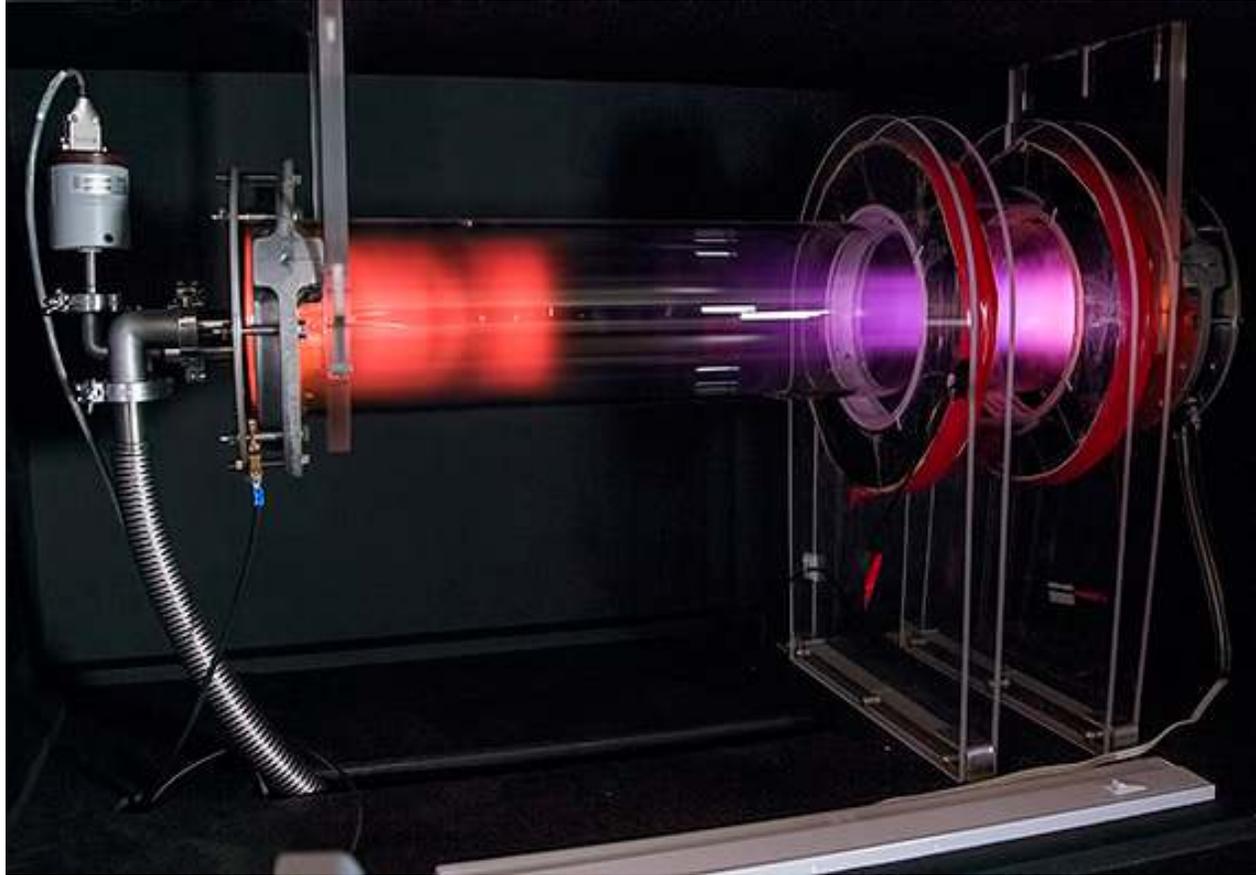

Reference: J.T. Gudmundsson & A. Hecimovic. *Foundations of DC plasma sources*. **Plasma Sources Science and Technology**, Volume 26, Number 12 (2017)

# PPPL's Remote Glow Discharge Experiment (RGDX)

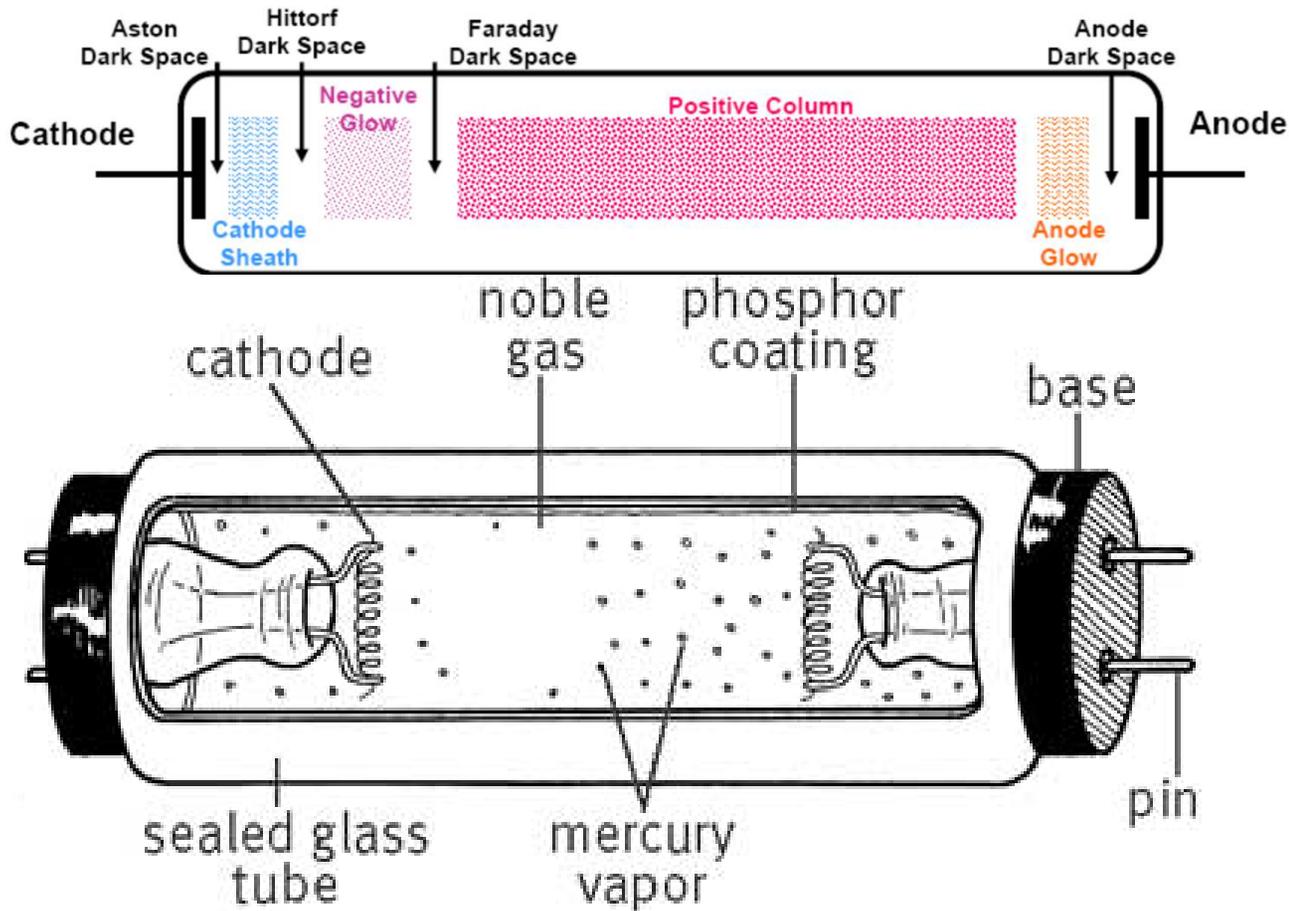

<https://www.pppl.gov/RGDX>

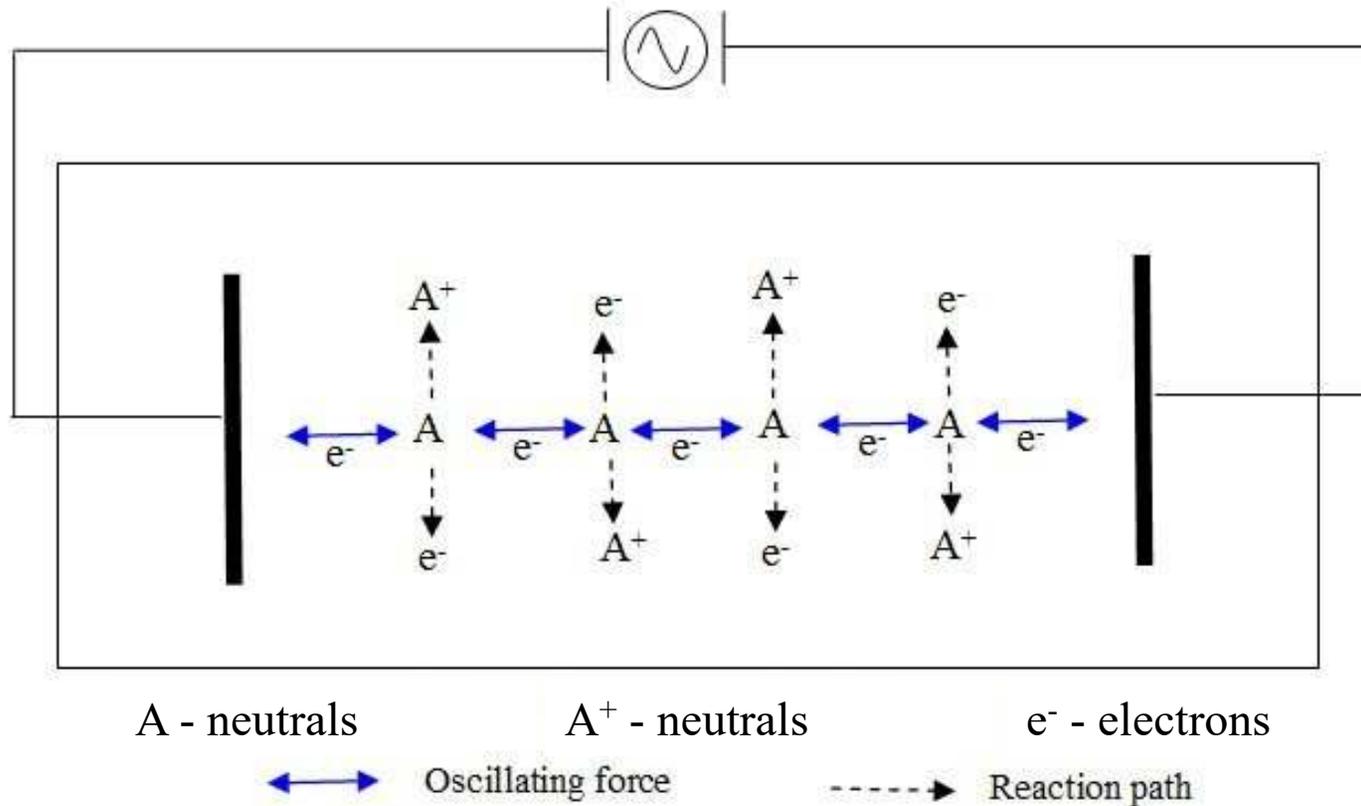

# Low-Pressure Glow Discharge Plasmas

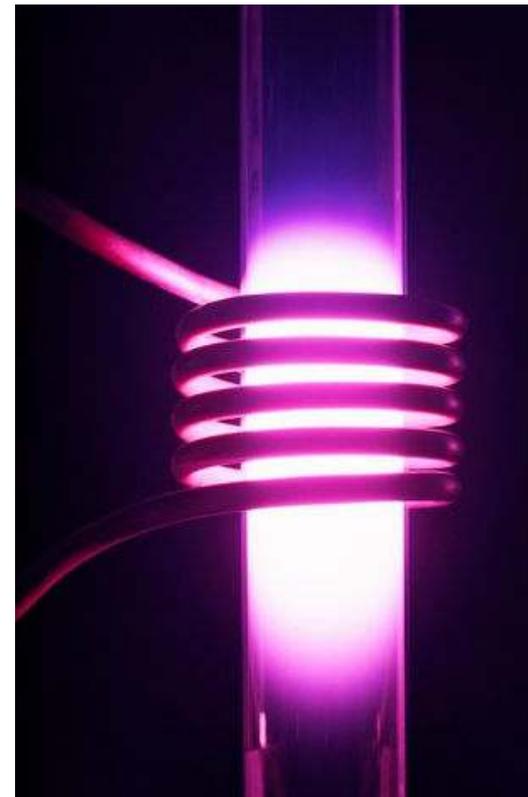

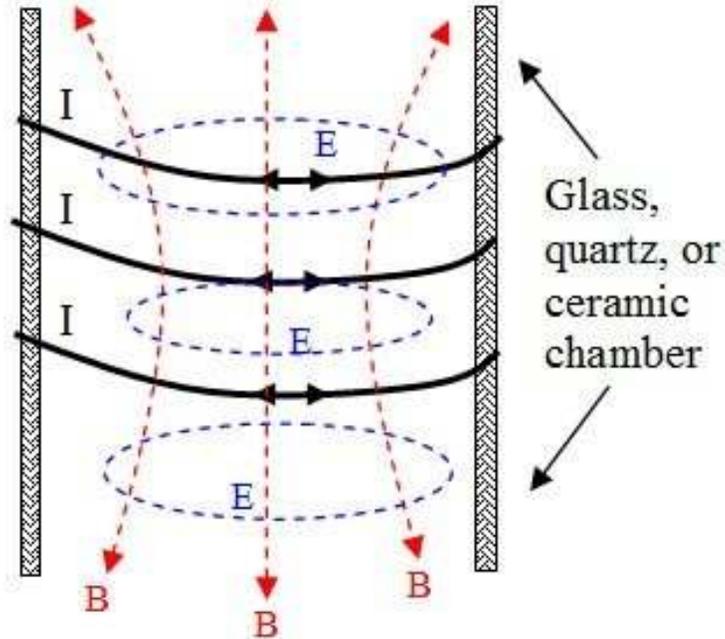

# Capacitively coupled plasma

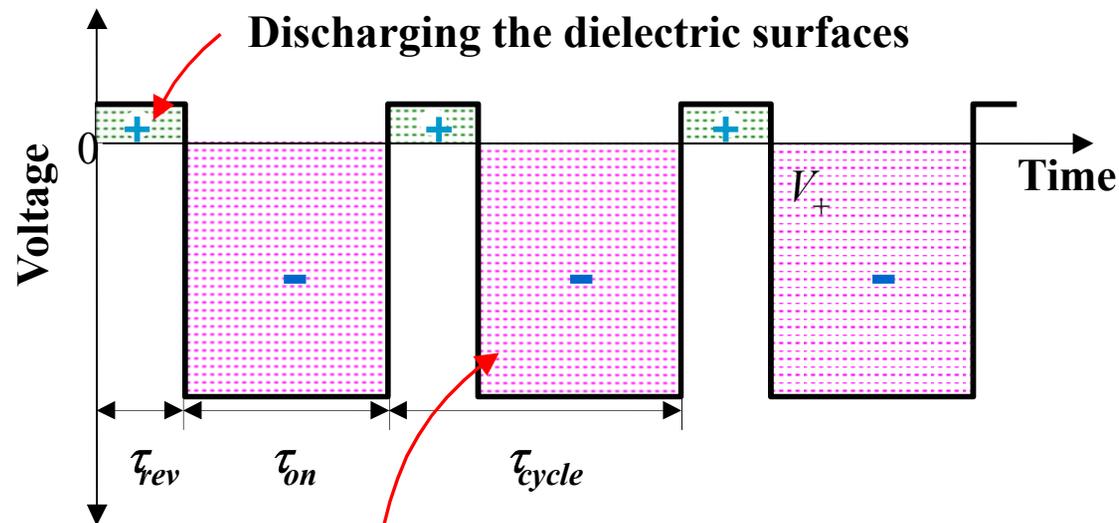

# Inductively Coupled Plasma

Frequency range: 10s kHz - 10s of MHz range

# Pulsed DC generated plasmas

**Sputter-deposition of dielectric layers,  
charging up dielectric surfaces**

- During operation with pulsed DC the potential on the dielectric (target) is periodically modulated, at a pulsing frequency  $f$ , typically between 1 to 350 kHz.
- For a certain *reverse time*,  $\tau_{rev}$  or *off time* at the beginning of each pulse, a positive reverse voltage is applied
  - this phase typically accounts for 10-50% of the pulse
- The remaining phase or *on time*,  $\tau_{on}$  accounts for 50-90% of each pulse.

# Pulsed DC generated plasmas

- The primary reason in the development and establishing of pulsed DC was the suppression of arcs at the target during reactive deposition.

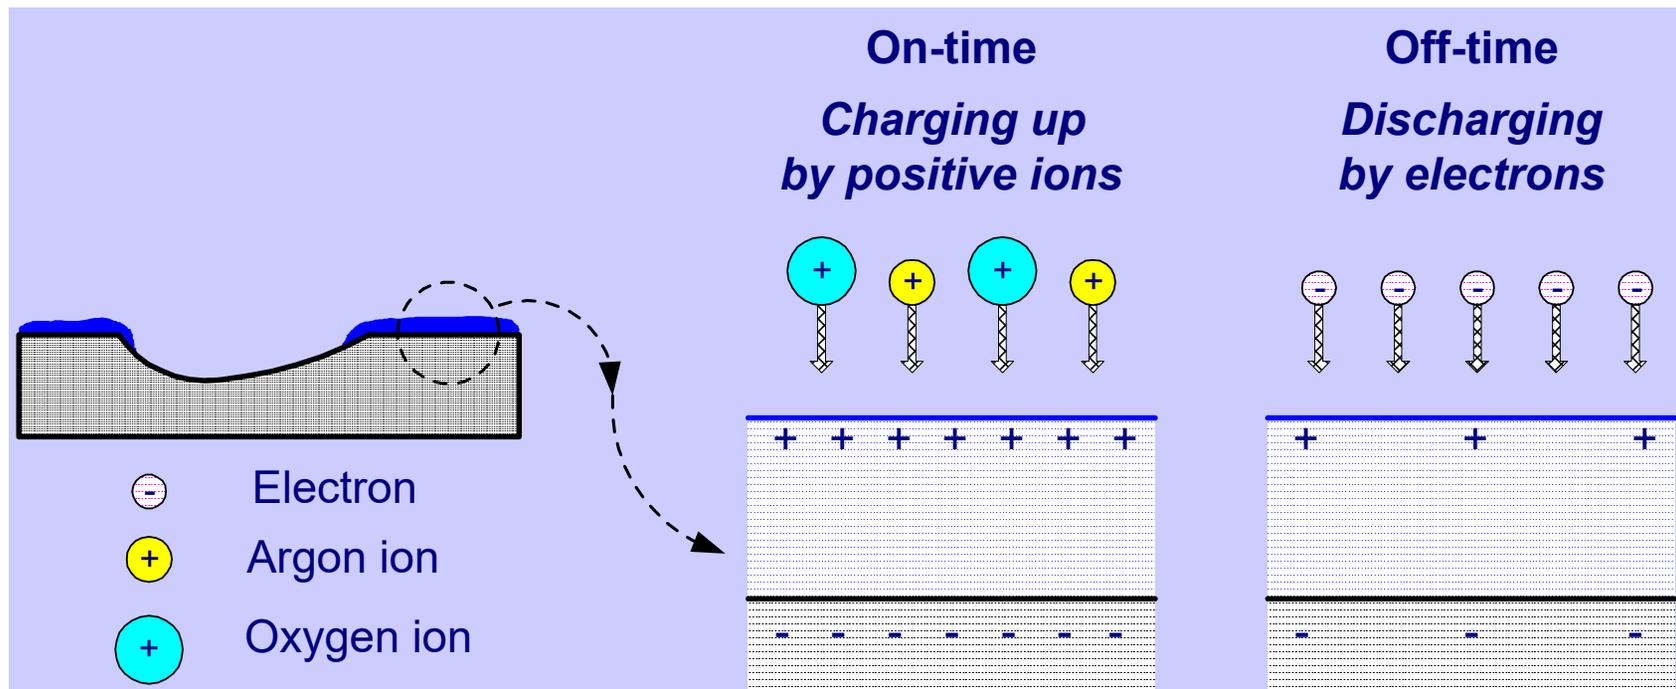

BASIC MECHANISM	RELATIVE FREQUENCY OF OCCURENCE
electric breakdown	10,000
microarc (unipolar arc)	100
arcing (bipolar arc)	1

- Research indicates that pulsing the discharge modulates the intrinsic plasma parameters.
- One of the most important parameters influencing the quality of deposited films is the energy of ions impinging on growing films.
  - Studies have shown a dependency of film properties on the selected pulsing frequency and reverse times.

# Pulsed DC generated plasmas

Charging up and discharging the dielectric surfaces

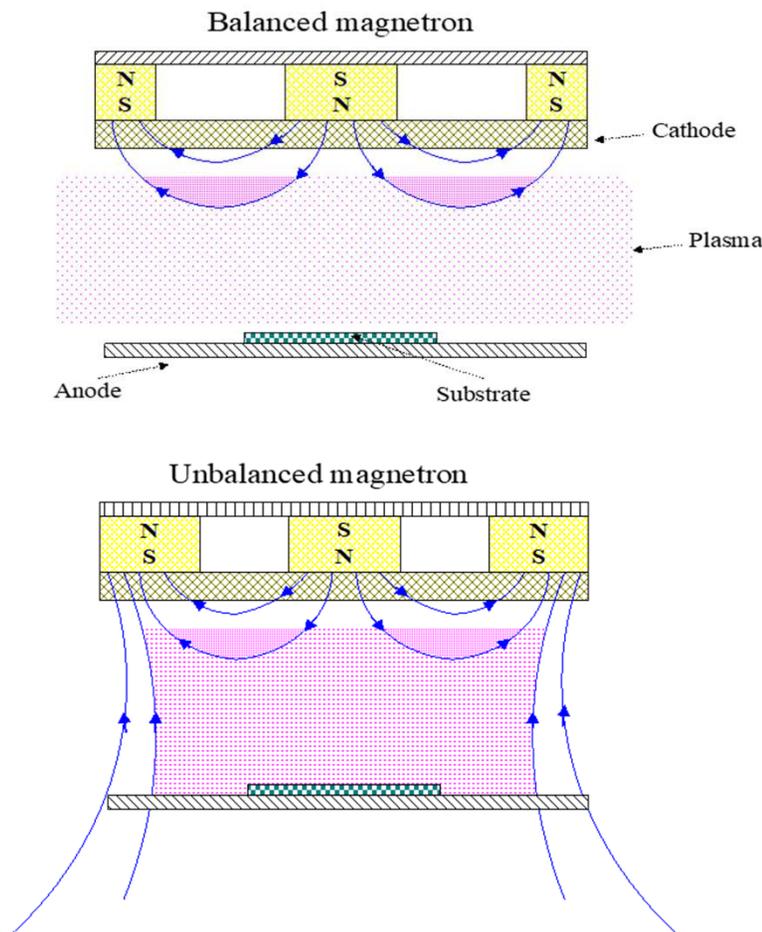

*When no arcing regime is maintained,  
discharging during each off-time is complete*

# Magnetron Introduction

## Balanced Magnetron

- one pole is positioned at the central axis of the target and the other pole is placed around the outer edge of the target forming closed or balanced field lines.
- In the balanced magnetron, the dense plasma is constrained near the target racetrack (~60 mm from the target surface)

## Unbalanced Magnetron

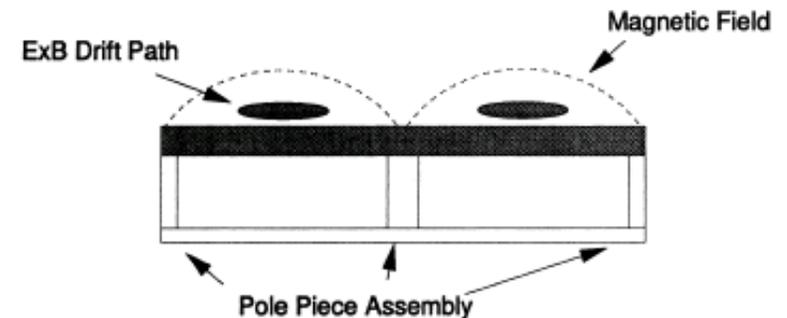

- outer magnets are stronger than ones in the center.
- some of the field lines from the edge magnets cannot be balanced by the center ones and have to be closed on themselves then causing the field lines to come down to the substrate
- Electrons move down to the substrate along these field lines with ions coming together as required by global plasma neutrality.
- higher ion flux onto the substrate compared to the balanced magnetrons.

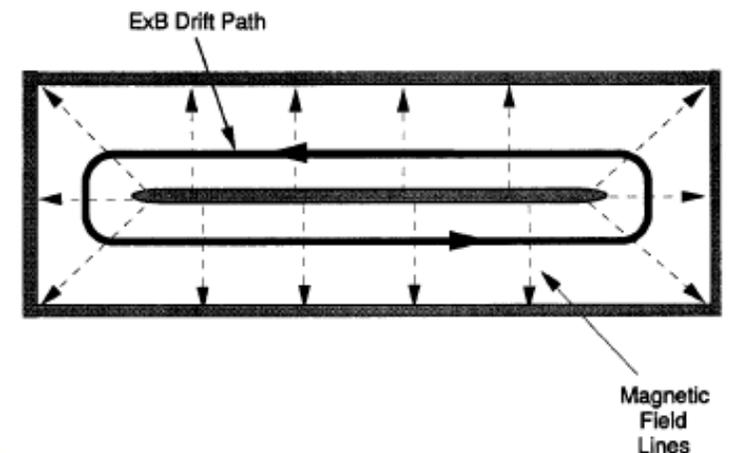

# Pulsed DC Unbalanced Planar Magnetron

- Secondary electrons move in a direction perpendicular to both the electric and magnetic field.
- the  $\mathbf{E} \times \mathbf{B}$  drift causes electrons to move parallel to the cathode surface in a direction 90 degrees away from the magnetic field.
- Secondary electrons lose their kinetic energy due to collisions with gas atoms (ionization) or with other electrons (electron heating), and the net result is an extremely dense plasma in this drift ring
- Ions in the drift region have a high probability of hitting the cathode. This results in even more production of secondary electrons and eventually very dense plasma

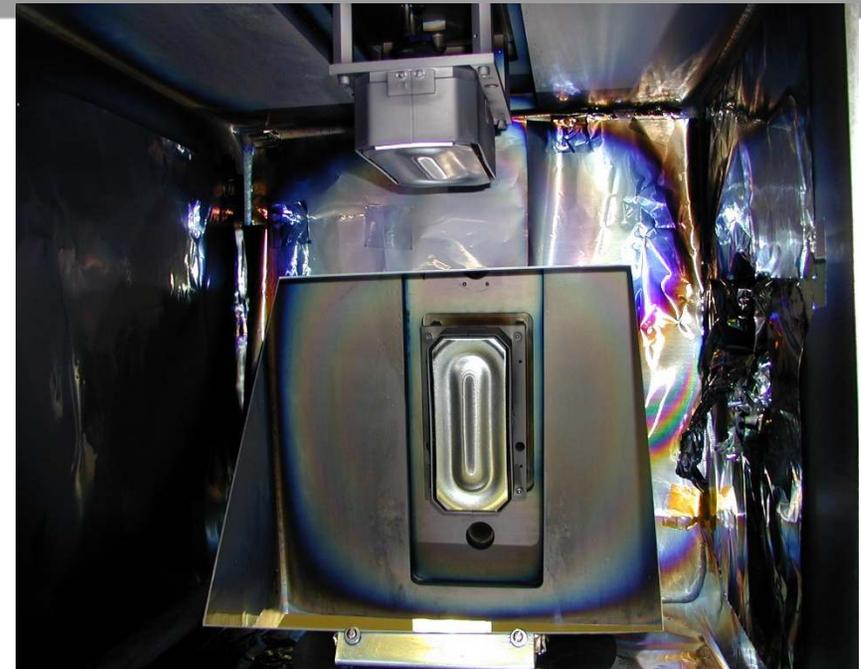

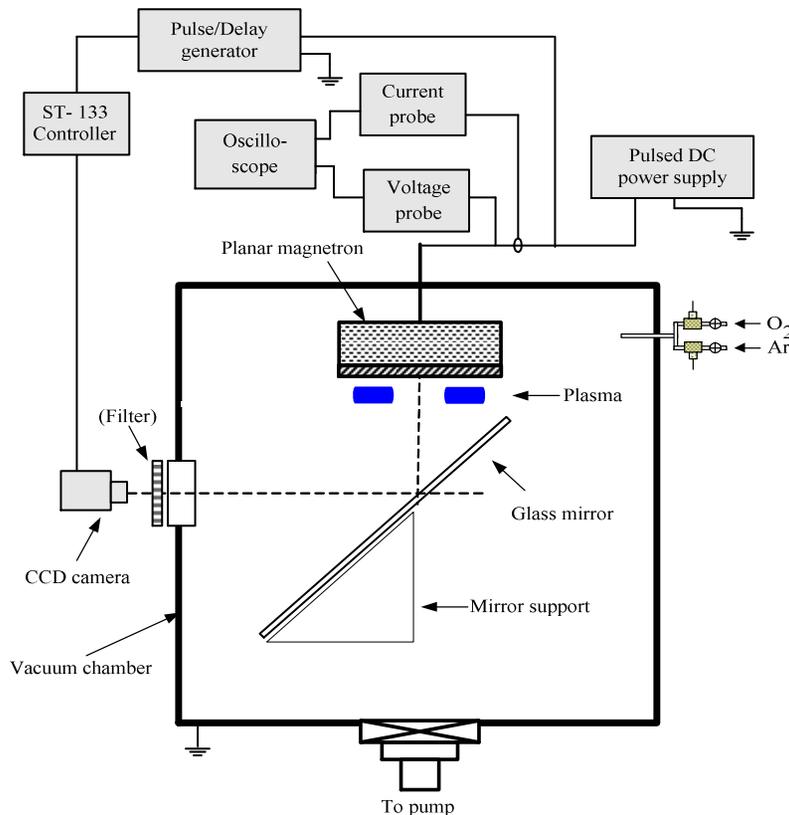

Top view

# Pulsed DC Unbalanced Planar Magnetron

Glow in opposite corners of dual anodes placed on the sides of a rectangular magnetron

# Low-Pressure, Low-Temperature Plasma Processing

Plasma processing of silicon for semiconductor manufacturing.

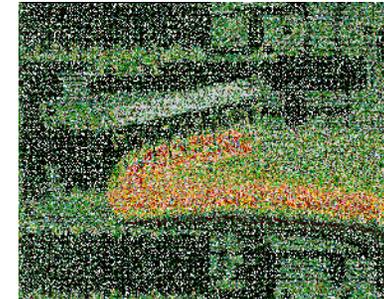

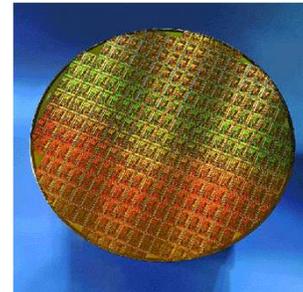

Plasma processing to harden or coat materials.

# Plasmas are easier to be generated at low pressures

Low pressure plasmas  
(1 mTorr ~ a few Torr)

- are well understood
- are used extensively nowadays (e.g. in semiconductor industry for computer chips manufacturing)

However, to generate low pressure plasmas:

- vacuum chambers
- expensive vacuum pumps
- pressure monitoring and pressure control devices

+

+

=

***Generate Plasmas at Atmospheric Pressure!!***

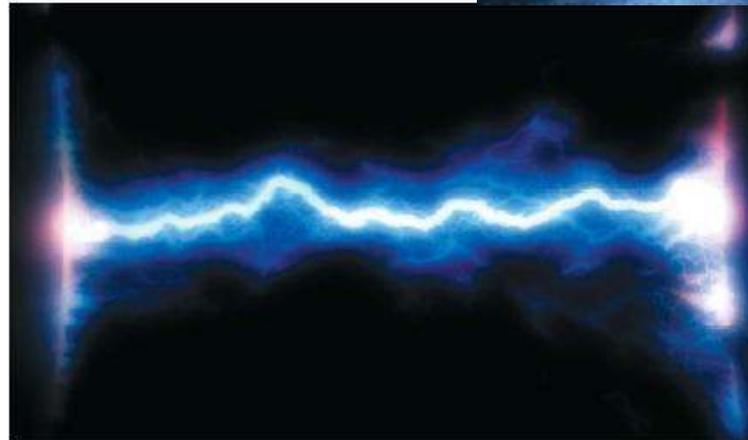

# What happens at air pressure?

- No vacuum is involved
- Difficult to generate and sustain
- Run into some challenges such as glow to *arc* transition – Non controllable

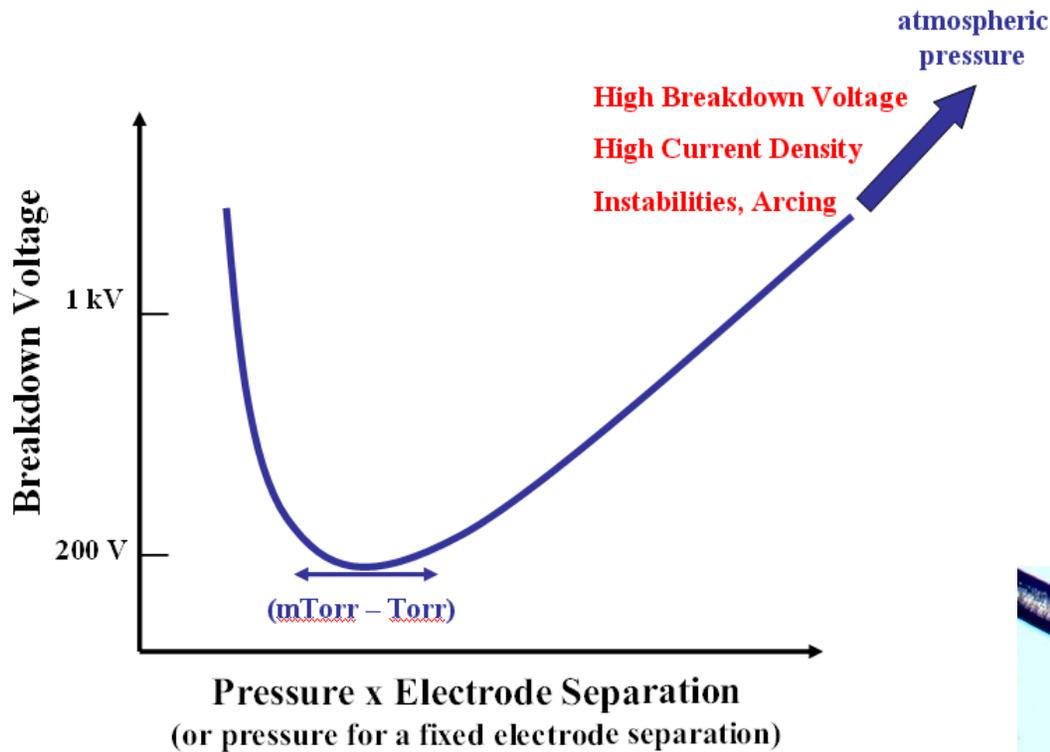

Arc Discharge: thermal plasma

- It's hot and detrimental
- Gas temperature can reach as high as  $2 \times 10^4$  K
- Low voltage drop at cathode
- High cathode current density

# Atmospheric (or higher) Pressure: Microplasmas

**Paschen Breakdown Curve**

Stabilization of high-pressure plasmas: “pd scaling”: “p” ↑, so “d” ↓ to keep breakdown voltage low and minimize instabilities after breakdown -

## Microplasmas

Dimension: a few millimeter down to and below **100 μm**

Human Hair: 60 – 100 μm

# How do we create stable atmospheric pressure, low temperature plasmas?

**Transient (pulsed) plasmas:** *In atmospheric plasmas, for efficient gas heating at least 100-1000 collisions are necessary. Thus, if the plasma duration is shorter than  $10^{-6} - 10^{-5}$  s, gas heating is limited. Of course, for practical purposes such plasma has to be operated in a repetitive mode, e.g., in trains of microsecond pulses with millisecond intervals.*

**Micro-confinement:** Gas heating occurs in the plasma volume, and the energy is carried away by thermal diffusion/convection to the outside. If the plasma has a small volume and a relatively large surface, gas heating is limited.

**Dielectric Barrier Discharges:** These plasmas are typically created between metal plates, which are covered by a thin layer of dielectric or highly resistive material. The dielectric layer plays an important role in suppressing the current: the cathode/anode layer is charged by incoming positive ions/electrons, which reduces the electric field and hinders charge transport towards the electrode. DBD also has a large surface-to-volume ratio, which promotes diffusion losses and maintains a low gas temperature.

# Single and double DBD

Single dielectric

Double dielectric

# Role of the Dielectric (Insulator)

The dielectric is the key for the proper functioning of the discharge.

Serves two functions:

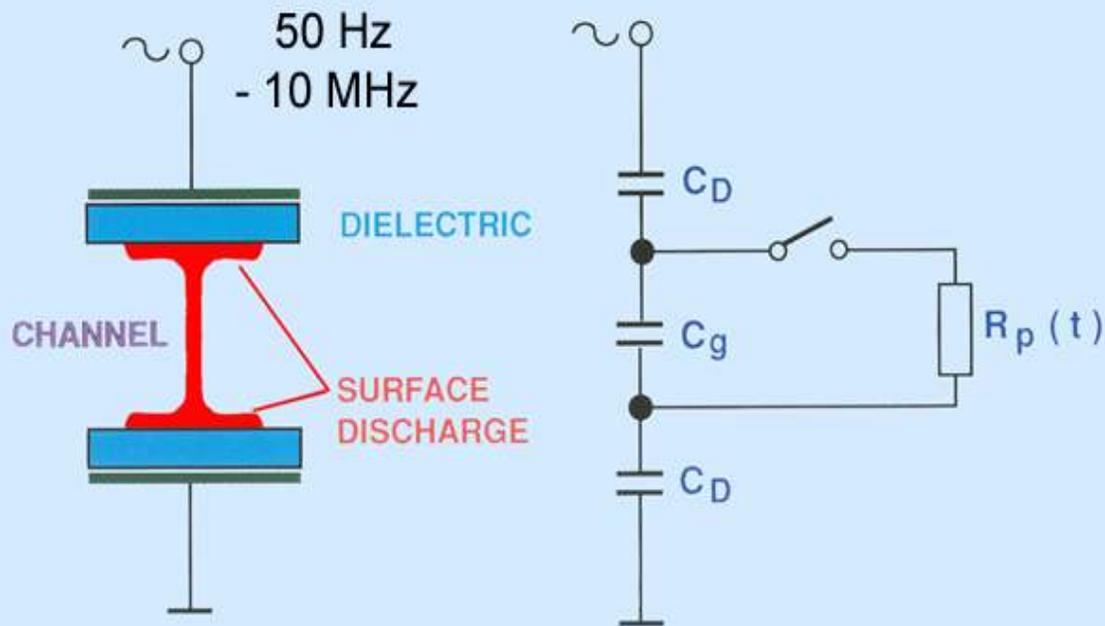

1. Limits the amount of charge transported by a single microplasma
2. Distributes the microplasmas over the entire electrode surface area

# Fundamental Operation of the Dielectric Barrier Discharge

- Many of relevant plasma processes that are of importance to achieving our goal occur on time scales that allow us to study them.
- Optical emission spectroscopic studies will allow us to determine the temporal and spatial development of important plasma species such as radicals (OH, NO, various oxygen radicals) with high time resolution (less than 10 ns) and a spatial resolution on the scale of mm in the plasma volume following pulsed plasma excitation.

Time scale of the relevant processes of the DBD.
